

IEEE 1905 Component

1. Introduction

IEEE 1905 is to have a mechanism that lets home devices discover each other and communicate. IEEE 1905 helps devices decide: thanks to the information that travels inside 1905 messages each node in the network knows the network topology, the speed of each interface, if there are congestion problems at some point , and then decides how to route traffic or even tells other devices how to route theirs.

1.1 Abstraction Layer

Abstraction layer is the component in charge of running the core protocol. It controls a node's interfaces and uses them to send periodic broadcast discovery messages to notify other ALs (running in other devices) about its presence.

1.2 High Layer Entity

High layer entity is the component that queries the AL (about all the information it has gathered using CMDUs) and then sends it control messages to modify its state (basically by creating/deleting new routing rules and/or changing the power state of one or more interfaces). These messages sent/received between one HLE and one AL are called "ALMEs".

The AL entity is executed like this:

```
$ ./al_entity -m <al_mac_address> -i <interfaces_list>
```

The HLE entity is executed like this:

```
$ hle_entity -a <ip address>:<tcp port> -m <ALME request type> [ALME arguments]
```

2. Source code organization:

At the root folder we have two folders (**src** and **output**) and two files ([README.md](#) and [Makefile](#))

```
-- Makefile  
-- README.md  
-- LICENSE  
-- PROJECT  
-- version.txt  
  
-- output  
  '-- tmp  
  
-- src
```

3. Execution:

```
root@TurrisOmnia-GW:/usr/bin#./al_entity -m D8:58:D7:00:A6:B5 -i eth0 -v 8888  
[000.000] WARNING : [PLATFORM] No platform flavour defined. Using default values when needed.
